*Accepted papers are articles in press that have gone through due peer review process and have been accepted for publication by the Editorial Board of the Serbian Archives of Medicine. They have not yet been copy-edited and/or formatted in the publication house style, and the text may be changed before the final publication.*

Although accepted papers do not yet have all the accompanying bibliographic details available, they can already be cited using the year of online publication and the DOI, as follows: the author’s last name and initial of the first name, article title, journal title, online first publication month and year, and the DOI; e.g.: Petrović P, Jovanović J. The title of the article. Srp Arh Celok Lek. Online First, February 2017.

When the final article is assigned to volumes/issues of the journal, the Article in Press version will be removed and the final version will appear in the associated published volumes/issues of the journal. The date the article was made available online first will be carried over.

Novel PANK2 mutation identified in patient with pantothenate kinase-associated neurodegeneration

Нова мутација у гену PANK2 код болесника са неуродегенерацијом удруженом са пантотенат киназом

SUMMARY

Introduction Pantothenate kinase associated neurodegeneration (PKAN) is a rare, recessively inherited disorder caused by mutations in the pantothenate kinase 2 (PANK2) gene on chromosome 20p13. The objective of this report is to present a patient with atypical PKAN with the novel heterozygous PANK2 mutation.

Case outline We present a 32-year-old female who had disease onset at the age 20 (depression, speech, chewing problems and backward falls) with progressive course. Neurological examination revealed hypomimia, risus sardonicus, dysphagia, tachylalia and severe dystonic dysarthria. Moderate arms, legs and jaw-opening dystonia, postural instability, urge incontinence and decreased visual acuity. A brain MRI revealed iron accumulation in the bilateral globus pallidus and putamen (“eye-of-the-tiger”), a radiological finding pathognomonic for PKAN. Genetic analysis revealed known mutation p.T528M (c.1583C>T) in exon 6, and novel p.Y405D (c.1213T>G) in exon 3 of PANK2 gene. In silico analyses strongly suggested this mutation to be pathogenic.

Conclusion We report a patient with PKAN, and novel substitution p.Y405D (c.1213T>G) in PANK2 that has not been previously described in PKAN patients.

Keywords: neurodegeneration with brain iron accumulation; pantothenate kinase-associated neurodegeneration; PANK2

INTRODUCTION

Pantothenate kinase associated neurodegeneration (PKAN) is a recessively inherited disorder caused by bi-allelic mutations in the pantothenate kinase 2 (PANK2) gene on chromosome 20p13 [1]. Two most frequent mutations (c.1231G > A, c.1253C > T) account for about one third of all cases, but to date, 155 different mutations have been reported [2].

Typical PKAN presents in early childhood with gait difficulty (spastic/dystonic gait), in almost 90% of patients, followed by generalized pyramidal and extrapyramidal features (mainly dystonia), neuropsychiatric involvement and pigmentary retinopathy. Clinical course is progressive and affected children generally become wheelchair-bound within a few years [3,4].
Atypical PKAN presents later with less pronounced motor involvement, but cognitive decline and psychiatric features may be prominent [5]. Disease progresses over first five years, followed by a long-lasting, rather stable period of slower progression [6].

In this report, we present a patient with atypical PKAN with the novel heterozygous PANK2 mutation.

CASE REPORT

A 32-year-old female, born from a non-consanguineous marriage, had unremarkable family history (brother was diagnosed as spondylitis ancylopoetica). Delivery and developmental milestones were normal. At the age of 20 she was treated by psychiatrist due to depression. At that time, she noticed speech, chewing problems and frequent backward falls. Three years later urge incontinence appeared and gradually worsened. Patient sought medical care at the Clinical Centres of Zagreb and Clinical Hospital in Osijek (Croatia) and Belgrade (Serbia). In the course of years, she experienced slow progression of symptoms and gradual but slight worsening of gait, speech and postural stability.

Laboratory findings examined in the course of her illness (since the beginning of symptoms until nowadays) included normal serum ferritin, ceruloplasmin, albumin, liver tests, copper (work up for Wilson s disease), and lipoprotein levels. The blood smear was negative for acanthocytes. After few years of disease, a brain MRI revealed onset iron accumulation in the bilateral globus pallidus and putamen (Fig. 1) (“eye-of-the-tiger”). We saw her after getting brain MRI, and due to typical “eye-of-the-tiger” finding we diagnosed her as NBIA (PKAN).

Personal neurological examination (neurological reports were also used for follow up of patients’ status) 12 years after disease onset, revealed hypomimia, risus sardonicus, dysphagia, tachylalia and severe dystonic dysarthria, moderate arms, legs and jaw-opening dystonia, postural instability and decreased visual acuity. Tendon reflexes were brisk, Babinski sign negative. Gait was unstable. Cerebellar signs and Romberg test were negative. The Mini Mental State Examination score was 30/30. Twelve years after symptoms onset she was still able to walk unassisted and to take care of herself.
Her psychological status was at the moment of examination within normal range without symptoms of depression.

DNA was extracted using commercial kit. After PCR amplification of \textit{PANK2} exon 5 and 6 and surrounding regions, direct Sanger sequencing was performed using BigDye Terminator v.3.1 Cycle Sequencing kit (Thermo Fisher Scientific – Life TECchnology, USA) on ABS 3500 Genetic Analyzer (ABS, USA). For data analysis Sequencher software has been used. After detection of only one heterozygous \textit{PANK2} mutation in exon 6, analysis was continued by Next Generation Sequencing (NGS) of DNA. We used TruSight One Panel (Illumina, USA) and MiSeq NGS platform (Illumina, USA). Data analysis was performed by Variant Studio provided for Illumina’s users. \textit{In-silico} characterization of detected gene variants was performed by PolyPhen, Shift, MetaLR, REVEL and Mutation Taster softwares. Confirmation of NGS detected \textit{PANK2} mutation was done by Sanger sequencing after PCR amplification of target region, as described above.

Initial targeted sequencing of selected \textit{PANK2} gene exons revealed known mutation p. T528M (c.1583C>T) in exon 6, in heterozygous state. In addition, NGS analysis detected substitution p.Y405D (c.1213T>G) in exon 3, also as a heterozygous change.

This change was confirmed in our patient by another targeted Sanger sequencing. Substitution c.1213T>G at transcript NM_153638.2 is the missense mutation leading to replacement of Tyrosine to Aspartic Acid at amino acid position 405. This change was not detected previously in population databases ExAC and 1000G and it is also absent from disease related bases ClinVar, LVOD and HGMD. The variant is located in exon 3 of the \textit{PANK2} gene that corresponds to catalytic domain of the protein, and this nucleotide and amino acid position is evolutionary highly conserved. According to in silico prediction p.Y405D (c.1213T>G) is ranged as deleterious (by Sift), probably damaging (by PolyPhen) or damaging (by MetaLR), likely disease causing (by REVEL) and disease causing (by Mutation Taster). Features mentioned above are sufficient to classify this variant as (likely) pathogenic [7].

DNA analysis revealed that proband’s neurologically healthy father and brother were a heterozygous carriers of known p.T528M (c.1583C>T), while healthy mother was a heterozygous carrier of the newly described p.Y405D (c.1213T>G) mutation.
DISCUSSION

Clinical presentation of our patient was consistent with atypical PKAN based on time of disease onset, neurological feature, presence of behavioural and psychiatric abnormalities and mode of disease progression. Besides characteristic MRI scans, mutational analysis confirmed the diagnosis.

Initial complaints were psychiatric, in accordance with the previous findings that psychiatric symptoms (depression, anxiety, emotional lability, tics, obsessive-compulsive disorder and psychosis) were common in the atypical PKAN, often preceding motor features [6, 8, 9].

DNA analysis showed one known mutation and one newly described variant in PANK2 gene. Substitution c.1583C>T (p.T528M) is one of the most common mutations in European NBIA patients, and confirmed founder mutation in Serbian population [10]. This variant affects catalytic domain of the enzyme; frequently it is associated with atypical form of PKAN supporting biochemical data of residual enzyme activity.

Substitution p.Y405D (c.1213T>G) has not been previously described in NBIA patients. Also, this variant was not found in population databases 1000 Genomes and ExAC nor in disease related databases such as ClnVar, LVOD and HGMD. Several in silico predictions indicate this variant is damaging. In addition, segregation analysis confirmed p.Y405D (c.1213T>G) is in trans with already known disease related mutation p.T528M, which all support its own pathogenicity.

Previous reports have demonstrated that in patients with two loss-of-function alleles, symptoms were always presented at an early stage of life, while those in atypical patients often resulted in amino acid changes. This indicated that many of patients with atypical form of the disease may have a residual PANK2 activities. It is believed that in the presence of missense mutations, residual activity of the PANK2 determines the age of onset, without playing a role in the progression of the disorder [11]. Although variable expressivity of alleles, as well as combination and concentration of the mutant proteins were the features that mainly affected PKAN phenotype, there were also other genetic and non-genetic modifiers that might alter PANK2 catalytic activity [12-15].
Although we were unable to determine the enzymatic activity of \textit{PANK2} in our case, these compound heterozygous mutations may have been responsible for the adult onset and delayed progressive nature of the disease. Our novel \textit{PANK2} mutation may probably add to understanding the clinic-genetic correlations in atypical PKAN.

\textbf{NOTE}

\textbf{Conflict of interest:} None declared.

\textbf{Ethical compliance statement:} We confirm that we have read the Journal’s position on issues involved in ethical publication and affirm that this work is consistent with those guidelines.

\textbf{Ethical standards:} All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. Written consent to publish all shown material was obtained from the patient.

\textbf{Funding sources:} This study was supported by the Ministry of Education, Science, and Technological Development of the Republic of Serbia (project no. 175090 to VK).

\textbf{Financial disclosures for previous 12 months:}

Marina Svetel has received speaker’s honoraria from Actavis.

Ivana Novaković, Svetlana Tomić, Nikola Kresojević report no sources of funding and no conflicts of interest.

Vladimir Kostić has received research grants from the Ministry of Education, Science, and Technological Development of the Republic of Serbia and the Serbian Academy of Sciences and Arts, and speaker honoraria from Actavis and Salveo.
