Pickwickian syndrome – the tip of the iceberg in extremely obese patients

Пиквик синдром – врх леденог брега код екстремно гојазних пацијената

Municipal Institution for Emergency Medical Care, Belgrade, Serbia

Received: February 22, 2019
Revised: November 24, 2019
Accepted: November 27, 2019
Online First: November 28, 2019
DOI: https://doi.org/10.2298/SARH190222130K

Accepted papers are articles in press that have gone through due peer review process and have been accepted for publication by the Editorial Board of the Serbian Archives of Medicine. They have not yet been copy edited and/or formatted in the publication house style, and the text may be changed before the final publication.

Although accepted papers do not yet have all the accompanying bibliographic details available, they can already be cited using the year of online publication and the DOI, as follows: the author’s last name and initial of the first name, article title, journal title, online first publication month and year, and the DOI; e.g.: Petrović P, Jovanović J. The title of the article. Srp Arh Celok Lek. Online First, February 2017.

When the final article is assigned to volumes/issues of the journal, the Article in Press version will be removed and the final version will appear in the associated published volumes/issues of the journal.

The date the article was made available online first will be carried over.

Pickwickian syndrome – the tip of the iceberg in extremely obese patients

**SUMMARY**

**Introduction** Pickwickian syndrome, also known as hypventilation syndrome in adults, consists of three factors: obesity (Body Mass Index – BMI >30 kg/m2), daytime hypercapnia and sleep disordered breathing, after ruling out other disorders that may cause alveolar hypventilation. Timely recognition of PS is of utmost importance because such patients have significant morbidity and mortality. However, most recent data indicate that PS is under-recognized and under-treated. We report a case of early-identified PS at pre-hospital level with a favorable outcome after hospital treatment.

**Case report** A 67-year-old female patient was diagnosed prehospitaly, and the diagnosis was later confirmed in hospital. Diagnostic criteria were as follows: BMI > 45.7 kg/m2 (height 170 cm, weight 132 kg), hypercapnia, hypoxemia and respiratory acidosis (pCO2 = 41 mmHg, pO2 = 56 mmHg, pH 7.45) in the absence of other causes of hypventilation. During hospitalization, the following diagnostic procedures were performed: standard laboratory analyses, chest radiography, electrocardiography, abdomen, and heart echocardiography. An attempted sleep study (polysomnography) was interrupted due to a drop in oxygen saturation levels. Non-invasive mechanical ventilation and diet were used as the first line of therapy. However, due to the development of a global respiratory insufficiency, the patient was intubated and placed on a mechanical ventilator. After 30 days of hospital treatment, the patient was released in a satisfactory general condition with recommendations for weight reduction and symptomatic therapy.

**Conclusion** As obesity is becoming an epidemic of modern society, early recognition and treatment of PS is of crucial importance.

**Keywords:** obesity, Pickwick, syndrome, early, recognition, treatment

**INTRODUCTION**

The increase in the prevalence of extreme obesity in the last decade is a health, economic and demographic problem of global proportions. Overweight and obesity cause 3.4 million deaths a year [1]. Classification of obese adults based on body mass index – BMI (obese class I - BMI 30.0-34.9; obese class II - BMI 35.0-39.9; obese class III - BMI ≥40.00)

DOI: https://doi.org/10.2298/SARH190222130K
and relative risk assessment of morbidity (elevated, moderately elevated and highly elevated) was made by WHO in 1997. [2]. According to the results of the 2013 Health Survey in the Republic of Serbia, based on the measured BMI, more than half (56.3%) of the population was overweight (35.1% pre-obese and 21.2% obese) [1]. The average BMI value in the adult population of Serbia is 26 ± 4.74 kg/m².

Among the many complications of obesity, respiratory tract disorders are in the shadow of metabolic and cardiovascular complications in the first place, so they have been extremely rarely mentioned in our surroundings [3]. Types of respiratory disorders in obese people may be different:

1. respiratory function disorders without alveolar hypoventilation,
2. obesity hypoventilation syndrome – OHS,
3. obstructive Sleep Apnea Syndrome – OSAS.
4. risk during and after surgical interventions [3].

OHS, also historically described as the Pickwickian syndrome (PS), is defined as daytime hypercapnia and hypoxemia (PaCO₂ > 45 mm Hg and PaO₂ < 70 mm Hg at sea level) in an obese patient (BMI > 30 kg/m²) with sleep-disordered breathing in the absence of any other cause of hypoventilation [4]. OHS is a diagnosis of exclusion. Other causes of hypoventilation, such as COPD; severe interstitial lung disease; mechanical respiratory limitation (for example, chest wall disorders such as kyphoscoliosis); myopathies (such as myasthenia gravis); neurological diseases; central causes (such as cerebrovascular disease and untreated hypothyroidism); and congenital causes (such as Ondine’s syndrome), should be ruled out. OHS often remains undiagnosed until late in the course of the disease. Its exact prevalence is unknown, but it has been estimated that 10% to 20% of obese patients with obstructive sleep apnea have hypercapnia [5]. Early recognition is important because these patients have significant morbidity and mortality. Effective treatment can lead to significant
improvement in patient outcomes, underscoring the importance of early diagnosis and early treatment [6].

We report a case of early-identified PS at pre-hospital level with a favorable outcome after hospital treatment.

CASE REPORT

An emergency medical service (EMS) team intervenes due to the severe choking of a 67-year-old female patient. She lives alone. The EMS doctor finds that the patient is extremely obese in central (android) type, BMI 45.7 kg/cm² (height 170 cm, weight 132 kg), moving with difficulty. In medical history, the patient states difficulties breathing, worsening in the lying position, fatigue even during minor activities, as well as all-day drowsiness. The problems have been more pronounced over the last seven days. Furthermore, she has urinary incontinence and "swollen stomach". The patient treats hypertension with fosinopril, which she takes irregularly. She has been smoking for the last 40 years (3 packs a day). The patient denies any loss of consciousness, allergies, previous pulmonary, otorhinolaryngological, neurological, cardiological, metabolic (diabetes mellitus) and endocrinological diseases, as well as chronic use of sedatives. On examination, the patient is mildly somnolent (Glasgow Coma Score 13), oriented, afebrile, dyspnoic (respiratory rate 20 / min), facial plethora, cyanotic (central cyanosis), anicteric. Severe patient aspect. Above the lungs weakened respiratory noise, crackles basal left, oxygen saturation (SaO2) 44%. Heart action is rhythmic, tones somewhat quieter. Blood pressure is 160/90 mmHg. The palpation of internal abdominal organs is difficult due to pronounced obesity. No peripheral edema. Electrocardiography (ECG): sinus rhythm, heart rate (HR) 110 / min, S wave in D1 and from V1 to V6, without acute changes in the ST segment. 100% O2 is applied through an oxygen
mask at a dose of 6 l/min. The patient was transported to hospital under the diagnosis of suspected PS.

On admission to hospital, the patient’s status remains unchanged, with slightly corrected SaO2 (58%). Gas analyses with no oxygen therapy when awake are: pO2 56mmHg, pCO2 41mmHg, ph 7.45. Due to the development of a global respiratory insufficiency (pO2 34mmHg, pCO2 67mmHg, ph 7.24) and the need for ventilatory support, the patient is moved to the Respiratory Unit. She is initially connected to non-invasive mechanical ventilation (NIV). Because of an inefficient gas exchange, the patient is intubated and placed on a mechanical ventilator. After being stabilized, the patient is extubated, connected to NIV and then on oxygen therapy.

Table 1 shows diagnostic procedures performed during hospitalization. Laboratory test results are shown in Table 2.

The treatment included: therapeutic diet (VLCD - very-low-calorie diet), crystalloid infusions, electrolytes, antibiotics (ceftazidime, moxifloxacin, vancomycin), anticoagulants (LMWH, then oral), ACE inhibitors, Ca antagonists, gastrointestinal agents and other symptomatic and supportive therapies.

Due to paroxysms of atrial fibrillation (Figure 1), amiodarone was included. The patient was converted to sinus rhythm with occasional AF paroxysms.

After 30 days of hospital treatment, the patient was released in a satisfactory general condition with recommendation of the following therapy: lifestyle interventions (dietary changes and physical exercise), amiodarone tbl. 200 mg 1x1 (five days), enalapril tbl. 10 mg 2x1, amlodipine tbl. 5 mg 1xa, furosemide tbl. 40 mg 1x1 with 1gr KCl, acenocoumarol tbl. 1x1 / 2 until INR medical check-up (goal INR between 2 and 3), pantoprazole tbl. 20 mg 1x1. Scheduled appointments with pulmonologist and cardiologist in 15 days, and glycemia and HbA1c tests in a month.
DISCUSSION

A high suspicion of PS is critical for setting the PS diagnosis [7]. Our patient fulfilled the clinical criteria (SpO2 44%, dyspnoea on exertion, but also at rest, in unbecoming and uncomfortable positions of the body, facial plethora, elevated level of bicarbonates in blood). According to some data, targeted anamnesis and/or heteroanamnesis have a high sensitivity of 90% to 100%, but significantly lower specificity: 50% to 70% [8]. Obesity per se leads to a greater likelihood of diseases such as systemic arterial hypertension, diabetes, dyslipidemia, and hypothyroidism [4]. Additional questions are directed towards sleep, snoring, daily somnolence, possible cyanosis, and pulmonary and cardiovascular symptoms. In physical examination, respiratory noises are mostly reduced due to a thick layer of subcutaneous tissue on the thorax. In uncomplicated cases, early inspiratory basal crackles can be detected (in our patient on the left side). Heart tones are usually quiet, but during the aggravation of the illness, there may be arrhythmia. The ECG finding in our patient indicates an atrial fibrillation that has been arrested with amiodarone. Frequent finding is arterial hypertension due to obesity, smoking, hypoxemia (in our case SaO2 was 44%), and other factors. Evidence of right ventricle enlargement from pulmonary hypertension that complicates advanced OHS may be seen on ECG and echo [9].

Obesity hypoventilation syndrome (OHS) cannot be diagnosed on history and examination alone but requires the demonstration of daytime hypercapnia [5]. Certain laboratory results complete the anamnesis and physical examination (elevated serum bicarbonate (> 27 mEq/L), hypercapnia (arterial pressure of carbon dioxide [PaCO2] > 45 mmHg), hypoxemia (PaO2 < 70 mmHg), polycythemia). Patients suspected of having OHS can initially be screened by pulse oximetry and by determination of serum levels of venous bicarbonate. SpO2 values < 93% on pulse oximetry would be suggestive of hypoventilation. A serum bicarbonate level ≥ 27 mEq/L had a sensitivity of 92% and a specificity of 50%,
justifying its use in screening [10]. A raised bicarbonate (> 27 mmol/L) or base excess (> 3 mmol/L) in the absence of another cause for a metabolic alkalosis in an obese individual with a PaCO₂ <45 mmHg may be an early indicator of OHS, warranting closer investigation [11]. We noted similarly. Blood tests are also recommended for the identification of hypothyroidism and polycythemia. A chest radiograph should be performed to exclude parenchymal lung disease, chest wall disease, asymmetrical elevation of a hemidiaphragm (ie, diaphragm paralysis), and cardiomegaly.

The "gold standard" for diagnosing OSAS is polysomnography (PSG), which involves non-invasive measurement of vital parameters during sleep. According to published allegations [9] 90% of PS patients have coexisting OSAS, however due to unsuccessful polysomnography and missing heteroanamnesis (the patient lived alone) we were unable to confirm this theory. Because symptoms are nonspecific, the diagnosis of PS is frequently delayed. It is commonly misdiagnosed as asthma or chronic obstructive pulmonary disease [12] and some patients are not diagnosed until hospitalization for acute-on-chronic respiratory failure occurs. However, recent data indicate the obesity hypoventilation syndrome is under-recognized and under-treated [13].

In our case, the diagnosis of PS was based on: BMI > 45.7 kg / m2, hypercapnia, hypoxemia and respiratory acidosis (pCO2 - 41mmHg, pO2-56mmHg, ph 7.45) in the absence of other causes of hypoventilation. Comorbidities such as heart failure, coronary artery disease, and cor pulmonale are more common in patients with OHS, and the likelihood that such patients will require invasive mechanical ventilation or ICU admission is also increased. Noninvasive positive airway pressure together with weight loss are the initial first line therapies for patients with OHS [14, 15]. After a global respiratory failure had developed, our patient was intubated and placed on a mechanical ventilator. Mortality rate in PS is increased due to the respiratory and cardiac consequences of obesity as such.
Because obesity has become a national epidemic, it is critical that physicians are able to recognize and treat obesity-associated diseases. OHS is still a poorly recognized entity in Serbia. Delayed diagnosis of OHS is associated with an increase in morbidity, mortality, and costs of care of patients who are more severely ill.

**Informed consent**

Written informed consent in Serbian for the case to be published (incl. images, case history and data) was obtained from the patient for publication of this case report, including accompanying images.

**Conflict of interest**: None declared.
